

FTP Credential Interception

```
(kali@abhi1)-[~]
$ sudo /etc/init.d/vsftpd start
[sudo] password for kali:
Starting vsftpd (via systemctl): vsftpd.service.

(kali@abhi1)-[~]
$ netstat -tulnp
(Not all processes could be identified, non-owned process info
will not be shown, you would have to be root to see it all.)
Active Internet connections (only servers)
Proto Recv-Q Send-Q Local Address           Foreign Address         State       PID/Program name
tcp6      0      0 :::21                  :::*                    LISTEN      -

(kali@abhi1)-[~]
$
```

Fig 1.1

In the above figure 1.1 we are initialising a directory (/etc/init.d) containing the scripts For managing the services and by saying **START** we are starting a **very secure FTP DAEMON server which allows the system as an FTP server.**

In the second line we use the command **netstat** for displaying the network statistics Tables etc..

-tulnp are some set of connections.

-t denotes the display of **TCP connections**

-u denotes the display of **UDP connections**

-l denotes the display of listening sockets where the system is expecting the incoming connections

-n denotes the numerical addresses for quick and clean outputs

-p denotes process id

Now by executing these it shows all the present listening network ports and starts listening to the FTP incoming sessions so as we can see that the local address is allotted with 21 port which is the default port for that server.

```

226 Directory send OK.
ftp> cd txtfiles
```

Fig 1.2

Now we are setting up an FTP server on a kali 2 machine using TCP dump and analysing the packet capture also using wireshark.

The command `cd txtfiles` to change the present directory to txtfiles based on the given name of the file (ABAs.txt).

`Pwd` stands for print working directory in this case it is `/home/abhi/textfiles` in the remote FTP server.

To list the contents (ABAs.txt) we use `dir` command with permission of `-rw-r -- r--`, this means that the owner now has read and write permission while the others only have read access.

The owner in the sense the machine creates a unique user identifier number (1002) and the group identifier number is also 1002 with a file size of 101 bytes with respective time frames in ABAs.txt file.

Now we are entering into the 229 extended passive mode to establish connection to the server with a port number 42321 for data connection.

```

```

Fig 1.5

To find the username we use the **grep command** which is used to log into the FTP server. In this case it is **abhi** and **password is kali** these credentials were transmitted in a very plain text which makes the session very weak and vulnerable.

-A stands for printing the packets in ASCII format for easy understanding.

Fig 1.6

We have started the wireshark analysis to complete the FTP session, so in task2.pcap file display we can see the source and destination Ip4v with TCP source port as 52076 and destination port of 21. we got the user as abhi in the **figure 2.6**

Fig 1.7

In figure 1.7 we can see the user and password details in plain text in the working directory of /home/abhi/ and entering extended passive mode (||54367|) we can see 150 opening port BINARY mode data and data connection and 226 means the transfer has completed.

Fig 1.8

In figure 1.8 we can see the user and password details in plain text in the working directory of /home/abhi/ and entering extended passive mode (|||25538|) we can see 150 opening port BINARY mode data and data connection, the command RETR ABAs.txt was for start downloading the file and 226 means the transfer has completed 221 quit.
